Received 4 June 2013; accepted 13 June 2013

Key indicators: single-crystal X-ray study;  $T = 296$  K; mean  $\sigma(\text{Pb}–\text{O}) = 0.003$  Å;  $R$  factor = 0.016;  $wR$  factor = 0.040; data-to-parameter ratio = 14.8.

The title compound, lead trimanganese tris(orthophosphate), has been synthesized by hydrothermal methods. In this structure, only two O atoms are in general positions and all others atoms are in the special positions of the *Imma* space group. Indeed, the atoms in the Wyckoff positions are namely: Pb1 and P1 on 4e (*mm2*); Mn1 on 4b (*2/m*); Mn2 and P2 on 8g (2); O1 on 8h (*m*); O2 on 8i (*m*). The crystal structure can be viewed as a three-dimensional network of corner- and edge-sharing  $\text{PO}_4$  tetrahedra and  $\text{MnO}_6$  octahedra, building two types of chains running along the *b* axis. The first is an infinite linear chain, formed by alternating  $\text{Mn}^{\text{III}}\text{O}_6$  octahedra and  $\text{PO}_4$  tetrahedra which share one vertex. The second chain is built up from two adjacent edge-sharing octahedra ( $\text{Mn}^{\text{II}}_2\text{O}_{10}$  dimers) whose ends are linked to two  $\text{PO}_4$  tetrahedra by a common edge. These chains are linked together by common vertices of polyhedra in such a way as to form porous layers parallel to (001). These sheets are bonded by the first linear chains, leading to the appearance of two types of tunnels, one propagating along the *a* axis and the other along *b*. The  $\text{Pb}^{\text{II}}$  ions are located within the intersections of the tunnels with eight neighbouring O atoms in form of a trigonal prism that is capped by two O atoms on one side. The three-dimensional framework of this structure is compared with similar phosphates such as  $\text{Ag}_2\text{Co}_3(\text{HPO}_4)(\text{PO}_4)_2$  and  $\text{Ag}_2\text{Ni}_3(\text{HPO}_4)(\text{PO}_4)_2$ .

## A new mixed-valence lead(II) manganese(II/III) phosphate(V): $\text{PbMn}^{\text{II}}_2\text{Mn}^{\text{III}}(\text{PO}_4)_3$

**Ghaleb Alhakmi, Abderrazzak Assani, Mohamed Saadi and Lahcen El Ammari**

### Comment

In a previous hydrothermal investigation of the system  $\text{A}_2\text{O}$ — $\text{MO}$ — $\text{P}_2\text{O}_5$ , we have succeeded to synthesize and structurally characterize new phosphate like  $\text{Ag}_2\text{M}_3(\text{HPO}_4)(\text{PO}_4)_2$  ( $\text{M} = \text{Co, Ni}$ ) which crystallizes in orthorhombic system with  $\text{Imma}$  space group (Assani *et al.*, 2011a, 2011b). The structure of this compound is an open frameworks such as that observed in the alluaudite. On the basis of crystallographic considerations, the later phosphates structure represents similarities with the well known alluaudite structure. Accordingly, both structures can be represented by the general formula  $\text{A}(1)\text{A}(2)\text{M}(1)\text{M}(2)_2(\text{PO}_4)_3$  as it has been established by Moore & Ito, 1979, in the case of alluaudite related compounds. This model is written according to decreasing size of the discrete sites. Mainly, the  $\text{A}$  sites can be occupied by either mono- or divalent medium-sized cations while the  $\text{M}$  cationic site corresponds to an octahedral environment generally occupied by the transition metal cations. This fact, particularly in the case of the alluaudite structure, has offered a great field of application as positive electrode in the lithium and sodium batteries (Trad *et al.*, 2010).

In accordance with the forefront of our research, a focus of investigation is associated with the mixed cation orthophosphates belonging to the above-mentioned compounds. Hence, by means of the hydrothermal method, we have recently synthesized and structurally characterized numerous phosphates corresponding to the general formula  $\text{A}(1)\text{A}(2)\text{M}(1)_2\text{M}(2)(\text{PO}_4)_3$  (Assani *et al.*, 2011c). The present paper is devoted to one of them, namely,  $\text{PbMn}^{2+}_2\text{Mn}^{3+}(\text{PO}_4)_3$ , with manganese mixed valence, rarely encountered in the literature (Adam *et al.*, 2009).

A partial three-dimensional plot of the crystal structure of the title compound is represented in Fig. 1, illustrating the connection of the metal-oxygen polyhedra. All atoms of this structure are in special positions, except two oxygen atoms ( $\text{O}3, \text{O}4$ ) in general position of the  $\text{Imma}$  space group. The crystal structure network consists of single phosphate  $\text{PO}_4$  tetrahedron linked to  $\text{MnO}_6$  octahedra, building two types of chains running along the  $b$  axis. The first chain is formed by an alternating  $\text{Mn}^{\text{III}}\text{O}_6$  octahedron and  $\text{PO}_4$  tetrahedron which share one vertex. The second chain is built up from two adjacent edge sharing octahedra ( $\text{Mn}^{\text{II}}_2\text{O}_{10}$ , dimers) whose ends are linked to two  $\text{PO}_4$  tetrahedra by a common edge. These two types of chains are linked together by common vertex of polyhedra to form porous sheets parallel to the  $(0\ 0\ 1)$  plane. The three dimensional framework delimits two types of tunnels parallel to  $a$  and  $b$  directions where the lead atoms are located as shown in Fig. 2. Each lead cation is surrounded by 8 oxygens.

Bond valence sum calculation lead(II) manganese(II/III) triphosphate(V):  $\text{PbMn}_3(\text{PO}_4)_3$  (Brown & Altermatt, 1985) for  $\text{Pb}^{2+}$ ,  $\text{Mn}^{13+}$ ,  $\text{Mn}^{2+}$ ,  $\text{P}^{15+}$  and  $\text{P}^{25+}$  ions are as expected, *viz.* 1.796, 3.042, 1.975, 5.014 and 4.843 valence units, respectively. The values of the bond valence sums calculated for all oxygen atoms are as expected in the range of 1.79–2.04 valence units. The three-dimensional framework of this structure is compared with some phosphates like  $\text{Ag}_2\text{M}_3(\text{HPO}_4)(\text{PO}_4)_2$  with  $\text{M} = \text{Ni}$  or  $\text{Co}$ , wherein the two  $\text{Ag}^+$  cations in the tunnels are replaced by  $\text{Pb}^{2+}$ .

## Experimental

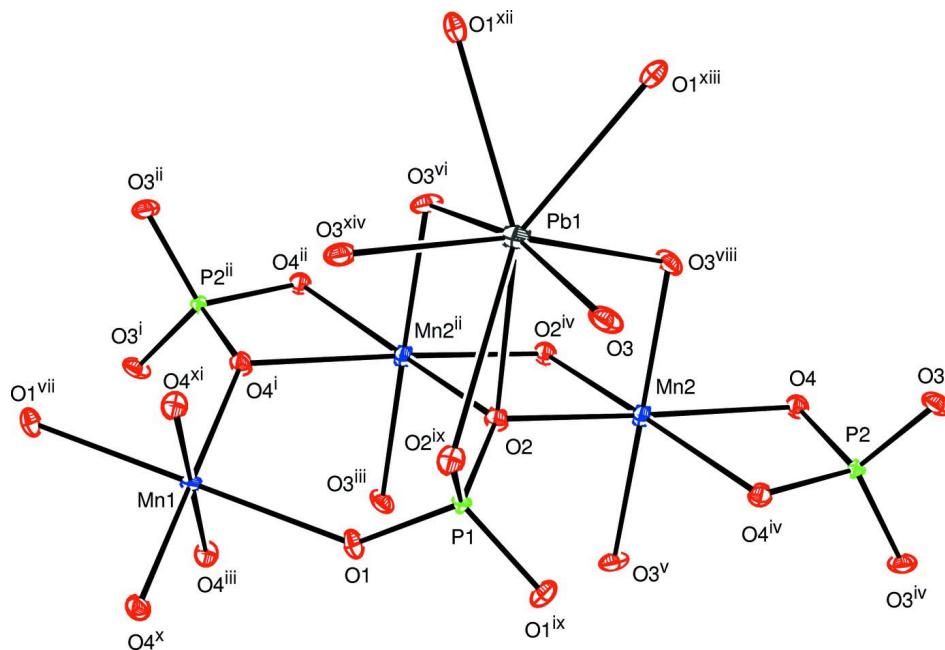

The crystal of the title compound is isolated from the hydrothermal treatment of the reaction mixture of lead, manganese and phosphate precursors in a proportion corresponding to the molar ratio  $\text{Pb}:\text{Mn}:P = 1:3:3$ . The hydrothermal reaction was conducted in a 23 ml Teflon-lined autoclave, filled to 50% with distilled water and under autogeneous pressure at 483 K for five days. After being filtered off, washed with deionized water and air dried, the reaction product consists of a brown sheet shaped crystals corresponding to the title compound besides a light brown powder.

## Refinement

The highest peak and the deepest hole in the final Fourier map are at 0.78 Å and 0.76 Å, respectively, from Pb1. The non-significant bonds and angles were removed from the CIF file.

$w = 1/[\sigma^2(F_o^2) + (0.0205P)^2 + 2.635P]$

where  $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} < 0.001$   
 $\Delta\rho_{\max} = 2.54 \text{ e \AA}^{-3}$

$\Delta\rho_{\min} = -0.98 \text{ e \AA}^{-3}$

*Special details*

**Geometry.** All s.u.'s (except the s.u. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell s.u.'s are taken into account individually in the estimation of s.u.'s in distances, angles and torsion angles; correlations between s.u.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell s.u.'s is used for estimating s.u.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against all reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2\sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on all data will be even larger.
